Introduction

Sentiment analysis is a technique used in Natural Language Processing (NLP) to determine the emotional tone behind a piece of text. It helps in identifying whether the text expresses a positive, negative, or neutral sentiment.

With the rapid growth of social media platforms, a large amount of data is generated every second. Analyzing this data helps organizations understand public opinion, customer feedback, and trending topics.

Real-time sentiment analysis allows continuous monitoring of user opinions as they are posted online. This is useful for businesses, governments, and organizations to make quick and informed decisions.

This project focuses on building a system that analyzes text input and classifies it into different sentiment categories using Python-based tools.

3. Objectives

- To analyze sentiment of social media-like text data
- To classify text as positive, negative, or neutral
- To simulate real-time sentiment analysis
- To visualize sentiment results using graphs
- To develop a simple user interface for interaction

4. Tools & Technologies Used

- **Python** – Programming language used for implementation
- **VADER Sentiment Analyzer** – For analyzing sentiment of text
- **Matplotlib** – For data visualization (graphs)
- **Streamlit** – For creating a simple web-based user interface

5. Methodology (Working Process)

The project follows a step-by-step process to analyze sentiment:

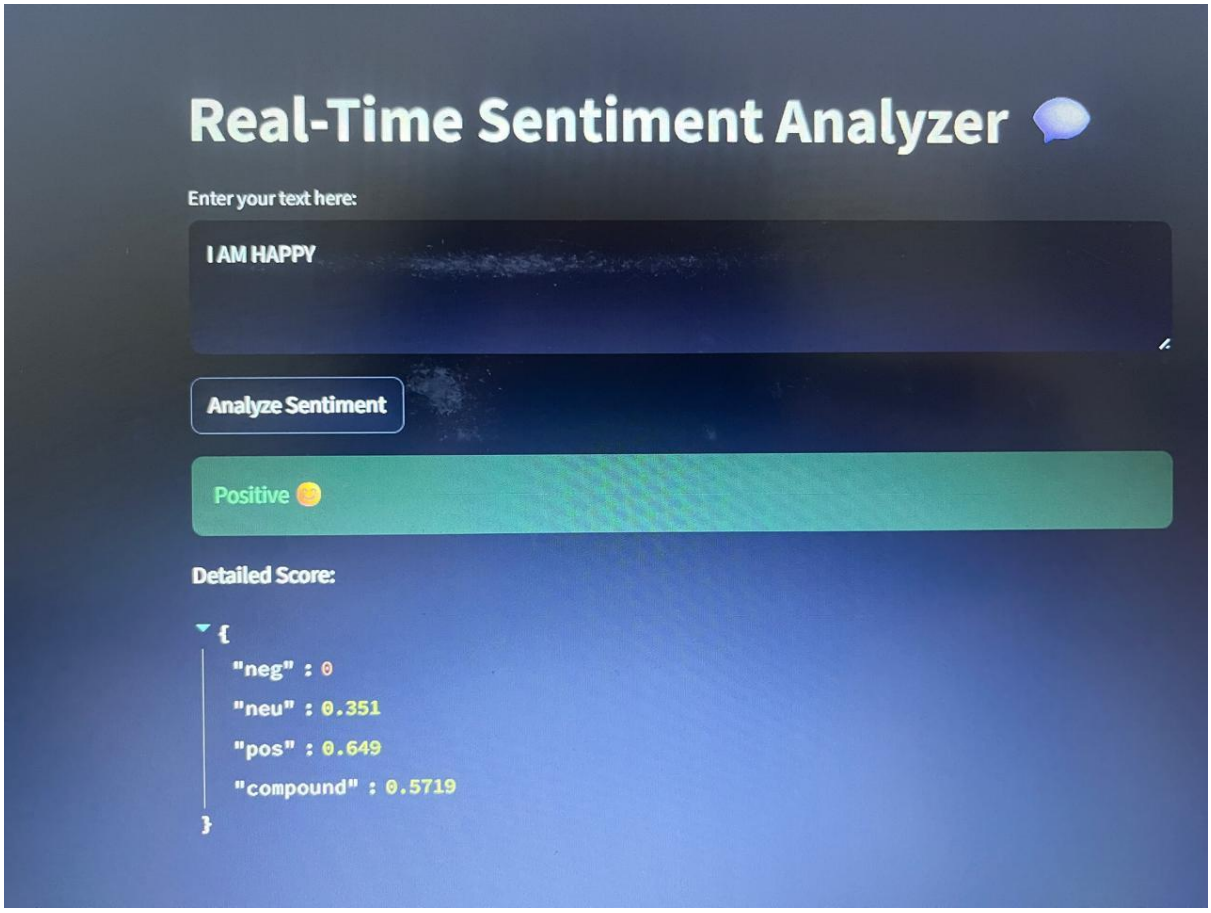
1. **Data Collection:**
   Text input is collected either manually or simulated as social media posts.
2. **Preprocessing:**
   The input text is cleaned and prepared for analysis.

3. **Sentiment Analysis:**
   The VADER sentiment analyzer processes the text and assigns sentiment scores.
4. **Classification:**
   Based on the compound score:
   - Positive (≥ 0.05)
   - Negative (≤ -0.05)
   - Neutral (between -0.05 and 0.05)
5. **Visualization:**
   The results are displayed using bar charts and UI components.

Output:

Post	**Sentiment**
I love this IPL match	Positive
This movie is terrible	Negative
AI is changing the world	Positive
I am not happy with the results	Negative
This is okay	Neutral
What an amazing performance	Positive
Worst experience ever	Negative
The event was average	Neutral

OUTPUT:



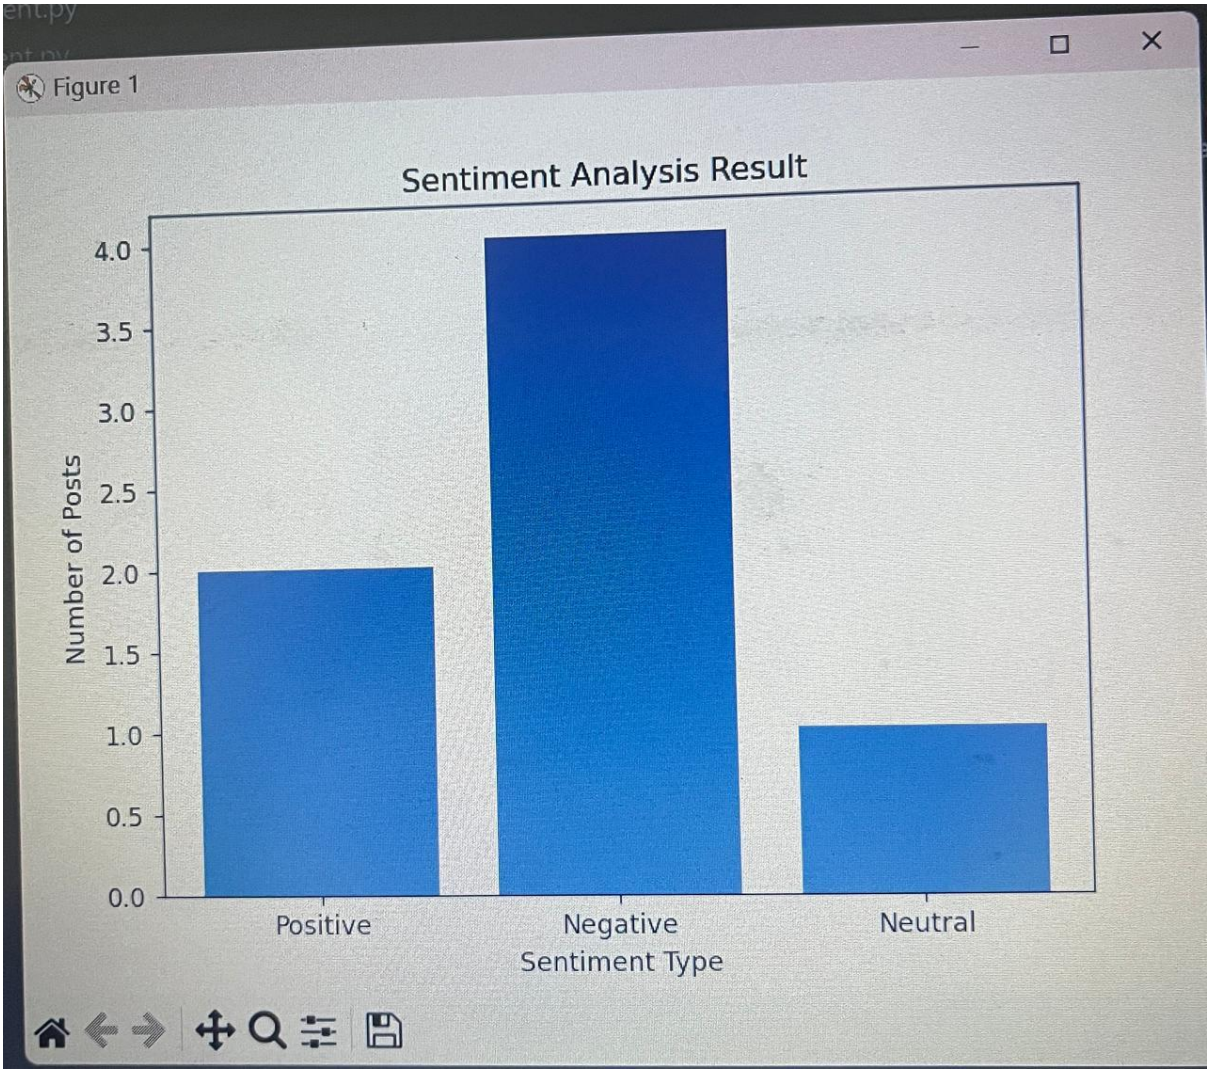
7. Result Visualization

The results of sentiment analysis are displayed using a bar chart. The graph shows the number of positive, negative, and neutral posts analyzed.

The visualization helps in quickly understanding the distribution of sentiments without reading each individual post.

For example:

- Positive posts may be higher during a successful event
- Negative posts may indicate dissatisfaction
- Neutral posts represent balanced opinions



8. Conclusion

In this project, a real-time sentiment analysis system was successfully developed using Python and NLP techniques. The system can analyze text input and classify it into positive, negative, or neutral categories.

The project demonstrates how sentiment analysis can be used to understand public opinion and trends from social media data. It also highlights the importance of data visualization in presenting analytical results effectively.

This type of system can be widely used in business decision-making, marketing strategies, and customer feedback analysis.
